Abstract

The genes of cellular cooperation that evolved with multicellularity about a billion years ago are the same genes that malfunction to cause cancer. We hypothesize that cancer is an atavistic condition that occurs when genetic or epigenetic malfunction unlocks an ancient 'toolkit' of pre-existing adaptations, re-establishing the dominance of an earlier layer of genes that controlled loose-knit colonies of only partially differentiated cells, similar to tumors. The existence of such a toolkit implies that the progress of the neoplasm in the host organism differs distinctively from normal Darwinian evolution. Comparative genomics and the phylogeny of basal metazoans, opisthokonta and basal multicellular eukaryotes should help identify the relevant genes and yield the order in which they evolved. This order will be a rough guide to the reverse order in which cancer develops, as mutations disrupt the genes of cellular cooperation. Our proposal is consistent with current understanding of cancer and explains the paradoxical rapidity with which cancer acquires a suite of mutually-supportive complex abilities. Finally we make several predictions and suggest ways to test this model.

derepresses

Somatic mutation model

"Natural selection occurs in neoplasms because (epi)genetic mutations generate heritable variation, and some mutations confer a selective advantage or disadvantage on the cell. All the hallmarks of cancer lead to the differential reproductive success of a clone." (Merlo et al 2006)

Cancer evolves during the lifetime of the patient.

Selection acting on (what is usually assumed to be) random variation produces the acquired capabilities of cancer.

acquired

Atavistic model

Natural selection occurs in neoplasms because (epi)genetic mutations damage regulation of otherwise repressed adaptive capabilities. These adaptive capabilities, when derepressed, show up as the hallmarks of cancer.

Cancer evolved ~ billion years ago and it is derepressed during the lifetime of the patient.

The capabilities of cancer are reacquired atavisms.

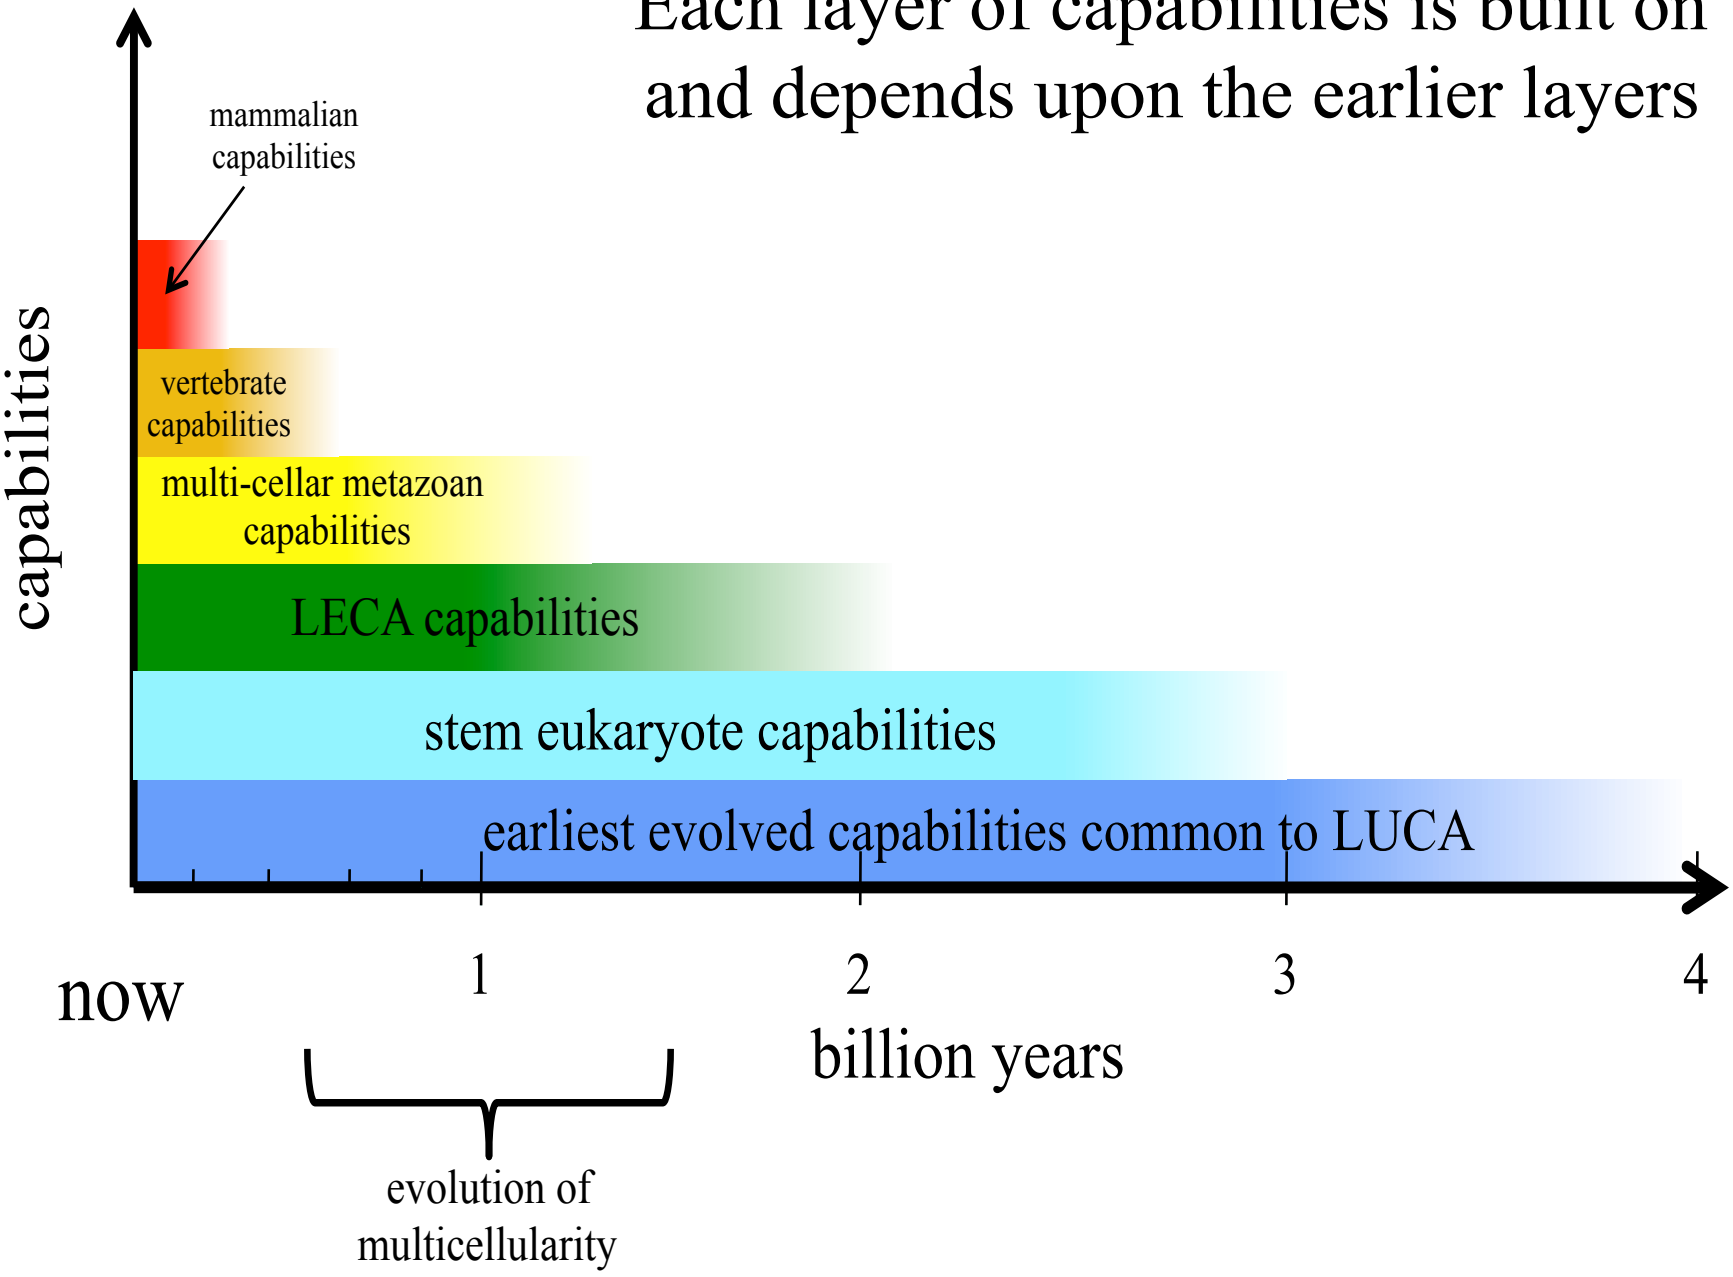
Each layer of capabilities is built on and depends upon the earlier layers



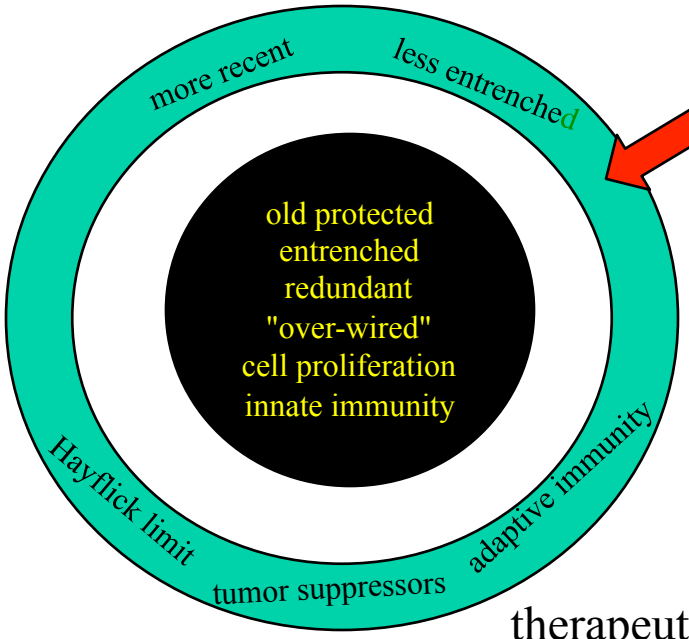
The Onion Model of differentially protected, conserved genes.

Atavistic model has therapeutic implications

Current therapeutic treatments predominantly target what cancer cells, and all cells, have deeply embedded in their genomes -- cellular proliferation. It may seem rational to treat a proliferative disease with antiproliferative drugs however, after ~ 4 billion years of evolution (the first ~ 3 billion of which were the largely unregulated proliferation of unicellular organisms) cellular proliferation may be the most protected, least vulnerable, most redundant and most entrenched capability that any cell has. The redundant and robust supports for cellular proliferation are ~ 2 billion years older than the many layers of recent differentiation and regulation that evolved with multi-cellular eukaryotes.

cancer as a castle-without-a-moat

normal cell



moat

cancer cell

therapeutic strategy: exploit the absence of the moat:
attack with fierce non-swimming warriors
they will drown when they try to attack normal cells

Target the Weakness Applied to ABC Pumps

Some ABC pumps are heavily implicated in multiple drug resistance.
All ABC pumps did not evolve at the same time.
Some are older, some are newer. Identify which is which.
Prediction of the Atavistic Model: in cancer cells the newer ones will be damaged and down-regulated compared to normal cells.
The older pumps will be up-regulated and responsible for cancer's abilities.
This seems to be true at the ~ 2 sigma level.
Therapy: identify the specific strengths of the new ones..ie they are more efficient at pumping out X. Attack cancer cells with X.
If these new pumps are missing in cancer, then cancer cells won't be able to pump out X. And they won't be able to mutate their missing pumps back into existence. And normal cells will be able to deal with X.

Table 1 | **Tissue localization and possible functions of ABC transporters**

Common Name	Systematic name	Tissue	Non-chemotherapy substrates	Chemotherapy substrates (known and suspected)	Defects in human disease	References
PGP/MDR1	ABCB1	Intestine, liver, kidney, placenta, blood–brain barrier	Neutral and cationic organic compounds, many commonly used drugs	Doxorubicin, daunorubicin, vincristine, vinblastine, actinomycin-D, paclitaxel, docetaxel, etoposide, teniposide, bisantrene, homoharringtonine (STI-571)	None known; altered sensitivity to drugs	8
MDR2	ABCB4	Liver	Phosphatidylcholine, some hydrophobic drugs	Paclitaxel, vinblastine	Progressive familial intrahepatic cholestasis	31,33,66,67
MRP1	ABCC1	All tissues	Glutathione and other conjugates, organic anions, leukotriene C4	Doxorubicin, epirubicin, etoposide, vincristine, methotrexate	None known	20–24
MRP2, cMOAT	ABCC2	Liver, kidney, intestine	Similar to MRP1, non-bile salt organic anions	Methotrexate, etoposide, doxorubicin, cisplatin, vincristine, mitoxantrone	Dubin–Johnson syndrome	24,60–63
MRP3	ABCC3	Pancreas, kidney, intestine, liver, adrenal glands	Glucuronate and glutathione conjugates, bile acids	Etoposide, teniposide, methotrexate, cisplatin, vincristine, doxorubicin	None known	37,38
MRP4	ABCC4	Prostate, testis, ovary, intestine, pancreas, lung	Nucleotide analogues, organic anions	Methotrexate, thiopurines	None known	39,40
MRP5	ABCC5	Most tissues	Nucleotide analogues, cyclic nucleotides, organic anions	6-Mercaptopurine 6-Thioguanine	None known	41,42
MRP6	ABCC6	Liver, kidney	Anionic cyclic pentapeptide	Unknown	Pseudoxanthoma elasticum (substrate unknown)	43–46,58
MXR, BCRP, ABC-P	ABCG2	Placenta, intestine, breast, liver	Prazosin	Doxorubicin, daunorubicin, mitoxantrone, topotecan, SN-38	None known	25–29,54
BSEP, SPGP	ABCB11	Liver	Bile salts	Paclitaxel	Progressive familial intrahepatic cholestasis	30,47,48, 64,65
ABCA2	ABCA2	Brain, monocytes	Steroid derivatives, lipids	Estramustine	Intracellular steroid transport	7,34,35

Targeting Cancer's Weaknesses (not its Strengths):
Therapeutic Strategies of the Atavistic Model.

by Charles H. Lineweaver, Paul C.W. Davies & Mark Vincent

…a therapeutic strategy for targeting cancer: design challenges that can *only* be met by the recently evolved capabilities no longer functional in cancer cells. One example of an exploitable weakness of cancer is the absence of an effective adaptive immune response in immunosuppressed tumor environments. This leaves tumor cells more vulnerable than healthy tissue, to pathogenic attack. Such a target-the-weakness therapeutic strategy has a broad application and contrasts with current therapies that target the main strength of cancer: cell proliferation.

cm. 1 2 3 4 5

Recipe for targeting the weakness.

The weakness is the absence of adaptive immunity in the tumor environment.

a) Identify a highly effective vaccine that protects the host organ (and the body in general) from a specific virus, bacterium or parasite that targets the host organ.

b) Vaccinate the patient (or verify that the patient has been previously vaccinated)

c) Inoculate the affected organ (specifically the tumors in the organ) with the disease-causing infectious agent at a dosage that will allow the vaccine-primed adaptive immune system to protect normal cells but, because of tumor immunosuppression, will be less able to protect tumor cells from the disease.

This therapy should be most effective in cases of strong immunosuppression. The more advanced the cancer, the more immunosuppressed the patient and the more difference there is between normal and tumor cells in terms of communication with the adaptive immune system. Thus, this therapy may complement standard cancer immunotherapies which are *least* effective in highly immunosuppressed patients.

In the case of metastasis: modify the approach of Quispe-Tintaya et al (2013). After vaccination against *Listeria*, an inoculation with *non-attenuated Listeria* is carried out. TAMs should be preferentially susceptible to attack from the *Listeria*, but normal macrophages at wound-healing sites will be relatively well-protected by the adaptive immune system. Since non-attenuated *Listeria* is not just the carrier but also the killer, *Listeria* reproduction increases its effectiveness with time.
No dilution of the killing agent (= radiation).

This is not Coley, BCG or immunotherapy.
The goal is not to induce an adaptive immunity response against the tumor.
The infectious agent is not attenuated.
